# Fixed Income Index Mathematics
## *Methodology*

March 2023

# Table of Contents

# Introduction

### Highlights

This document covers the mathematics of fixed income index calculations, including how they are calculated, how coupon payments are handled, and how other adjustments are made to the index. For details on a specific index, please refer to that index's methodology document available at *www.spglobal.com/spdji/*.

### Different Varieties of Indices

A majority of S&P Dow Jones fixed income indices are market value weighted, where each bond's weight in the index is proportional to its market value. Sometimes an index has capping requirements which set the target weights for the index securities. An additional weight factor (AWF) is used to make market value adjustments to the index securities in order to satisfy the capping rules.

# Index Calculations

**Daily Index Values**

Index values are calculated each day by applying the current day's index return to the previous day's index value, as follows:

$$TRIV_t = TRIV_{t-1} * (1 + IndexTR_t) \quad (1)$$

$$PRIV_t = PRIV_{t-1} * (1 + IndexPR_t) \quad (2)$$

$$IRIV_t = IRIV_{t-1} * (1 + IndexIR_t) \quad (3)$$

where:

| | | |
|---|---|---|
| $TRIV_t$ | = | Total return index value on day *t*. |
| $PRIV_t$ | = | Price return index value on day *t*. |
| $IRIV_t$ | = | Interest return index value on day *t*. |
| $IndexTR_t$ | = | Index total return on day *t*. |
| $IndexPR_t$ | = | Index price return on day *t*. |
| $IndexIR_t$ | = | Index interest return on day *t*. |

**Daily Index Returns**

The individual index security returns are aggregated to calculate returns for the index. Specifically, on a given day, the total return, interest return, and price return for the index are equal to a weighted average of the returns of the securities that constitute the index. The weight of each index security return is equal to the relative weight of that security in the index as of the previous trading day (adjusted for principal pre-payments, etc.). Each cash security has a foreign exchange return related to the index currency as its price return and zero as its interest return. The formulae are as follows:

$$IndexTR_t = \sum_i SecurityWeight_{i,t-1} * tr_{i,t} \quad (4)$$

$$IndexPR_t = \sum_i SecurityWeight_{i,t-1} * pr_{i,t} \quad (5)$$

$$IndexIR_t = \sum_i SecurityWeight_{i,t-1} * ir_{i,t} \quad (6)$$

where:

| | | |
|---|---|---|
| $IndexTR_t$ | = | Index total return on day *t*. |
| $IndexPR_t$ | = | Index price return on day *t*. |
| $IndexIR_t$ | = | Index interest return on day *t*. |
| $tr_{i,t}$ | = | Total return of index security *i* on day *t* ($ir_{i,t} + pr_{i,t}$). |
| $pr_{i,t}$ | = | Price return of index security *i* on day *t*. |
| $ir_{i,t}$ | = | Interest return of index security *i* on day *t*. |
| $SecurityWeight_{i,t-1}$ | = | Adjusted market value weight of index security *i* at the close of day *t-1*. |

**Total Return**

The total return, *TR,* for a given security on day *t* is the sum of the market price, interest, and FX return on day *t*:

$$TR_t = IR_t + PR_t \quad (7)$$

where:

$IR_t$ = Interest return on day *t*.

$PR_t$ = Price return on day *t*.

Price return measures the return due to the change in the market price of the security. Interest return (or coupon return) includes the return due to the interest earned on that security. In the case of zero coupon bonds, the accretion in price due to interest return is reported as price return.

**Interest Return**

The formula for the interest return on an individual index security on day *t* is as follows:

$$IR_t = (AI_t - AI_{t-1} + \text{Cpn}_t) \diagup DirtyPrice_{t-1} \quad (8)$$

where:

$IR_t$ = Daily interest return for the security on day *t*.

$AI_t$ = Accrued interest, up to and including day *t*.

$DirtyPrice_{t-1}$ = Dirty price of the security on day *t-1*.[1]

$Cpn_t$ = Coupon payment* on day *t*.

** For securities trading ex-dividend, the coupon is recognized on ex-dividend date. Securities in default do not accrue interest.*

**Interest Return (Loans)**

In the following formula, *PAR* should be treated as (*AWF*PAR*). The formula for the interest return on an individual index loan on day *t* is as follows:

$$IR_t = \frac{(PAR_t * R_t)/360}{MV_{Beg}} \quad (9)$$

where:

$IR_t$ = Interest return on day *t*.

$PAR_t$ = Par amount of the index loan as of the last weekly rebalancing, adjusted for principal pre-payments, etc., up to and including day *t*.

$R_t$ = Interest rate on day *t*.

$MV_{Beg}$ = Market value, at the beginning of day *t*.

**Index Interest Rate**

The index interest rate is determined by the weighted average spread to LIBOR/SOFR/EURIBOR/SONIA.

[1] The dirty price of a security is defined as the sum of the market quoted price and the interest deemed to be earned on that security, but not yet paid to the investor. The clean price is the market quoted price without accrued interest.

**Price Return**

The formula for the price return for an index security on day *t* is as follows:

$$PR_t = (CleanPrice_t - CleanPrice_{t-1} - FX\ return) \diagup DirtyPrice_{t-1} \quad (10)$$

where:

$PR_t$ = Price return for the security on day *t*.

$CleanPrice_t$ = Market quoted price for the security without accrued interest on day *t*.

$DirtyPrice_{t-1}$ = Market quoted price for the security with accrued interest on day *t-1*.

**Price Return (Loans)**

The formula for the price return for an index loan on day *t* is as follows:

$$PR_t = \frac{PAR_t * \left(\frac{P_t - P_{t-1}}{100}\right) + Prin_t * \frac{RP - P_{t-1}}{100}}{MV_{Beg}} \quad (11)$$

where:

$PR_t$ = Price return on day *t*.

$PAR_t$ = Par amount of the index loan as of the last weekly rebalancing, adjusted for principal pre-payments, etc., up to and including day *t*.

$P_t$ = Loan price on day *t*.

$P_{t-1}$ = Loan price on the previous day.

$Prin_t$ = Principal pre-payments, etc., on day *t*.

$MV_{Beg}$ = Market value, beginning of day *t*.

$RP$ = Redemption price.

Note that the formula for the Price Return (11) itself has two components. The first term, in the numerator on the left side, represents the unrealized return due to any change in the price, while the second term (on the right) represents the realized return due to receiving a principal repayment at the Redemption Price (which could differ from par) rather than at the current end of day price.

**Unhedged Return**

Total unhedged return measures the return by converting the local currency return of the underlying securities to the index currency. The formula for the unhedged daily return for a security is composed of its local currency return and the foreign currency return.

$$TR_{UH,t} = \left(1 + R_{L,t}\right) * \left(1 + \frac{FX_t - FX_{t-1}}{FX_{t-1}}\right) - 1 \quad (12)$$

where:

$TR_{UH,t}$ = Total unhedged return on day *t*.

$R_{L,t}$ = Total local currency return on day *t*.

$FX_t$ = Foreign exchange spot rate on day *t*.

$FX_{t-1}$ = Foreign exchange spot rate on day *t-1*.

**Hedged Return**

Hedged return measures the return by hedging currency risk through a one-month forward currency contract. The formula for the hedged return for an index is shown as follows:

$$HedgedMTD_t = H_t + H_t * \left(\frac{S_0}{F_{0,30}} - \frac{S_t}{F_{t,30-t}}\right) + (1 + BaseMTD_t - H_t) * \frac{S_0}{S_t} \quad (13)$$

$$TR_{H,t} = \left(\frac{HedgedMTD_t}{HedgedMTD_{t-1}}\right) - 1 \quad (14)$$

where:

| | |
|---|---|
| $TR_{H,t}$ | = Total hedged return on day t |
| $HedgedMTD_t$ | = Month to date hedged return on day t |
| $BaseMTD_t$ | = Month to date return of the local currency index on day t |
| $S_t$ | = Foreign exchange spot rate on day t |
| $F_{0,30}$ | = Forward rate on the rebalancing date 0 with 30 days remaining in the contract, assuming a 30/360 day count convention. |
| $F_{t,30-t}$ | = Interpolated forward rate on day t with 30-t days remaining in the contract |
| $H_t$ | = Hedge size on day t |

**Hedge Size**

The hedge size is determined by using the index weighted yield of the pro forma index on the rebalancing day. Assuming the yield is an annual return proxy, the size of the monthly hedge is a projection of the monthly return of the local currency index. The hedging size used for a MTD calculation on day t is shown by $H_t$.

$$HedgeSize = 1 + \left(\frac{yield}{2}\right)^{1/6} \quad (15)$$

$$H_t = HedgeSize^{t/30} \quad (16)$$

**Market Value**

The market value of the security as represented in the index as of the close on day *t* is calculated as follows:

$$MV_t = PAR_t * \frac{(P_t + AI_t)}{100} * FX_t \quad (17)$$

The adjusted market value is applied as follows:

$$AMV_t = AWF * MV_t \quad (18)$$

where:

| | |
|---|---|
| $MV_t$ | = Market value of the index security on day *t*. |
| $AMV_t$ | = Adjusted market value of the index security on day *t*. |
| $PAR_t$ | = Par amount of the index security as of the last rebalancing, adjusted for principal pre-payments, etc., up to and including day *t*. |

$P_t$ = Clean price of the index security on day *t*.

$AI_t$[2] = Accrued interest on the index security, up to and including day *t*.

$FX_t$ = Foreign exchange rate used to convert to the target currency on day *t*.

*AWF* = Additional weight factor.

If the valuation date is not a trading day, the market value is based on the price as of the immediate prior trading day, plus interest accrued to the valuation date. On the cash payout day, the accrued interest is set to the coupon cash value.

**Additional Weight Factor**

The Additional Weight Factor (AWF) is used to tilt the original market value weight of a security within the index. It is calculated on the rebalancing reference date and is implemented on the rebalancing effective date. The AWF remains static until the subsequent rebalancing.

The AWF for all market value-weighted indices is equal to 1. For target weighted indices, the AWF is calculated as follows:

$$AWF_i = TW_i * \frac{\sum_1^N MV_i}{MV_i} \quad (19)$$

where:

$AWF_i$ = Additional weight factor of the index security *i*.

$TW_i$ = Target weight for the index security *i*.

$MV_i$ = Market value of the index security *i* in the underlying index.

$\sum_1^N MV_i$ = Aggregate market value of all *N* securities in the underlying index.

In equal-weight indices *TW* = 1/*N*, where *N* is the number of securities included in the index.

**Weight**

The relative weight of an index security *i* is defined as the adjusted market value of that security expressed as a percentage of the aggregate adjusted market value of all the securities in the index portfolio, as follows:

$$weight_i = \frac{AMV_i}{\sum_i AMV_i} \quad (20)$$

**Yield to Maturity Adjustment for Inflation-linked Securities[3]**

To calculate the yield to maturity adjustment, one has to project the inflation rate for future cash flows of the bond. The projected inflation rate is an approximation of future inflation and is calculated using the following formula:

$$Projected\ inflation\ Rate_t = 100 * (\frac{CPI_t}{CPI_{t-1year}} - 1) \quad (21)$$

where:

[2] For loans, $AI_t$ is calculated on a 360-day basis. Accrued interest is reduced to zero every 90 days after a loan enters the index.
[3] Nominal yield is applied to inflation/index-linked securities only.

$CPI_t$ = The reference national CPI for day *t* is calculated through a linear interpolation of the two most recent CPI levels available as of the start of the month.

$CPI_{t\text{-}1year}$ = The reference national CPI as of one year before the valuation date *t* with the same interpolation as $CPI_t$.

Using the projected inflation rate, the current index ratio and the nominal cash flows, we generate the expected inflated cash flows, which are then used to calculate the nominal yield.

**Hedge Adjusted Yield**

The hedge adjusted yield represents the yield of an index after accounting for the cost of hedging foreign currency exposure in the forward market. At each rebalance, a projected market value using the pro-forma index yield is hedged using the forward rate. The hedge adjusted yield accounts for the premium or discount of the forward rate and applies it to the yield used to project the future market value as follows:

$$\textit{Hedge adjusted yield}_i = \text{Yield}_{i,t} + \left(\frac{FF_{0,30}}{FX_t} - 1\right) * 12 \quad (22)$$

Where:

$\text{Yield}_{i,t}$ = The index weighted yield found in the rebalancing day's pro-forma universe

$FF_{0,30}$ = Forward rate on the last rebalancing date 0 with 30 days remaining in the contract, assuming a 30/360 day count convention.

$FX_t$ = Foreign exchange spot rate on day *t*.

**Performance Disclosure/Back-Tested Data**

Where applicable, S&P Dow Jones Indices and its index-related affiliates ("S&P DJI") defines various dates to assist our clients in providing transparency. The First Value Date is the first day for which there is a calculated value (either live or back-tested) for a given index. The Base Date is the date at which the index is set to a fixed value for calculation purposes. The Launch Date designates the date when the values of an index are first considered live: index values provided for any date or time period prior to the index's Launch Date are considered back-tested. S&P DJI defines the Launch Date as the date by which the values of an index are known to have been released to the public, for example via the company's public website or its data feed to external parties. For Dow Jones-branded indices introduced prior to May 31, 2013, the Launch Date (which prior to May 31, 2013, was termed "Date of introduction") is set at a date upon which no further changes were permitted to be made to the index methodology, but that may have been prior to the Index's public release date.

Please refer to the methodology for the Index for more details about the index, including the manner in which it is rebalanced, the timing of such rebalancing, criteria for additions and deletions, as well as all index calculations.

Information presented prior to an index's launch date is hypothetical back-tested performance, not actual performance, and is based on the index methodology in effect on the launch date. However, when creating back-tested history for periods of market anomalies or other periods that do not reflect the general current market environment, index methodology rules may be relaxed to capture a large enough universe of securities to simulate the target market the index is designed to measure or strategy the index is designed to capture. For example, market capitalization and liquidity thresholds may be reduced. In addition, forks have not been factored into the back-test data with respect to the S&P Cryptocurrency Indices. For the S&P Cryptocurrency Top 5 & 10 Equal Weight Indices, the custody element of the methodology was not considered; the back-test history is based on the index constituents that meet the custody element as of the Launch Date. Back-tested performance reflects application of an index methodology and selection of index constituents with the benefit of hindsight and knowledge of factors that may have positively affected its performance, cannot account for all financial risk that may affect results and may be considered to reflect survivor/look ahead bias. Actual returns may differ significantly from, and be lower than, back-tested returns. Past performance is not an indication or guarantee of future results.

Typically, when S&P DJI creates back-tested index data, S&P DJI uses actual historical constituent-level data (e.g., historical price, market capitalization, and corporate action data) in its calculations. As ESG investing is still in early stages of development, certain datapoints used to calculate certain ESG indices may not be available for the entire desired period of back-tested history. The same data availability issue could be true for other indices as well. In cases when actual data is not available for all relevant historical periods, S&P DJI may employ a process of using "Backward Data Assumption" (or pulling back) of ESG data for the calculation of back-tested historical performance. "Backward Data Assumption" is a process that applies the earliest actual live data point available for an index constituent company to all prior historical instances in the index performance. For example, Backward Data Assumption inherently assumes that companies currently not involved in a specific business activity (also known as "product involvement") were never involved historically and similarly also assumes that companies currently involved in a specific business activity were involved historically too. The Backward Data Assumption allows the hypothetical back-test to be extended over more historical years than would be feasible using only actual data. For more information on "Backward Data Assumption" please refer to the FAQ. The methodology and factsheets of any index that employs backward assumption in the back-tested history will explicitly state so. The methodology will include an Appendix with a table setting forth the specific

data points and relevant time period for which backward projected data was used. Index returns shown do not represent the results of actual trading of investable assets/securities. S&P DJI maintains the index and calculates the index levels and performance shown or discussed but does not manage any assets.

Index returns do not reflect payment of any sales charges or fees an investor may pay to purchase the securities underlying the Index or investment funds that are intended to track the performance of the Index. The imposition of these fees and charges would cause actual and back-tested performance of the securities/fund to be lower than the Index performance shown. As a simple example, if an index returned 10% on a US $100,000 investment for a 12-month period (or US $10,000) and an actual asset-based fee of 1.5% was imposed at the end of the period on the investment plus accrued interest (or US $1,650), the net return would be 8.35% (or US $8,350) for the year. Over a three-year period, an annual 1.5% fee taken at year end with an assumed 10% return per year would result in a cumulative gross return of 33.10%, a total fee of US $5,375, and a cumulative net return of 27.2% (or US $27,200).
